BlackRock

Financial Risk Analysis with Python

Project Objective:

Analyze Customer Transaction Data to Identify Financial Risks & Insights

Tools Used:

Google Colab

By: Harivansh Dogne

Project Title

Financial Risk Analysis with Python - Blackrock

Objective

Develop a **Customer Financial Behavior and Risk Analysis Report** using Python to clean, organize, and analyze BlackRock's customer account data. The report aims to uncover transaction patterns and risk indicators to support better customer strategy and financial decision-making.

Dataset Description

The dataset contains customer account information including transaction frequency, account balances, and transaction amounts. The dataset is used to understand customer behavior and financial risk patterns.

Key Tasks

• Data Cleaning and Preprocessing
• Exploratory Data Analysis (EDA)
• Customer Segmentation (High / Medium / Low Activity)
• Financial Risk Identification
• Hypothesis Testing
• Data Visualization

Tools and Technologies Used

• Python
• Pandas
• NumPy
• Matplotlib
• Seaborn
• Google Colab

Expected Outcome

The project will provide insights into customer transaction behavior and help identify potential financial risks through statistical analysis and visualization.

Author

Harivansh Dogne

Date

March 2026

Video Explaination Link

https://drive.google.com/file/d/1aCbUqV3paS0LfIaao1t8JmdheUqgxSNb/view?usp=sharing

 Task 1: Data Cleaning and Formatting

*Remove/treat any special characters or non-numeric enties from financial fields.

*Convert currency amounts into numerical format.

*Validate and format date columns.

*Ensure account types and transaction categories are standardized.

```
# Step 1: Import Libraries & Load Data
from google.colab import files
upload = files.upload()
```

```
<IPython.core.display.HTML object>
```

```
Saving blackrock.csv to blackrock.csv
```

```
import pandas as pd
import numpy as np

# Load dataset
df = pd.read_csv("blackrock.csv")

# Preview Data
df.head(10)
```

```
{"summary":"{\n  \"name\": \"df\",\n  \"rows\": 800,\n  \"fields\": [\n  {\n  \"column\": \"TransactionID\",\n  \"properties\": {\n  \"dtype\": \"number\",\n  \"std\": 58,\n  \"min\": 1,\n  \"max\": 199,\n  \"num_unique_values\": 195,\n  \"samples\": [\n  121,\n  39,\n  29\n  ],\n  \"semantic_type\": \"\",\n  \"description\": \"\"\n  }\n  },\n  {\n  \"column\": \"CustomerID\",\n  \"properties\": {\n  \"dtype\": \"category\",\n  \"num_unique_values\": 180,\n  \"samples\": [\n  \"CUST8874\",\n  \"CUST9843\",\n  \"CUST7887\"\n  ],\n  \"semantic_type\": \"\",\n  \"description\": \"\"\n  }\n  },\n  {\n  \"column\": \"AccountID\",\n  \"properties\": {\n  \"dtype\": \"category\",\n  \"num_unique_values\": 192,\n  \"samples\": [\n  \"ACC20297\",\n  \"ACC67701\",\n  \"ACC92104\"\n  ],\n  \"semantic_type\": \"\",\n  \"description\": \"\"\n  }\n  },\n  {\n  \"column\": \"AccountType\",\n  \"properties\": {\n  \"dtype\": \"category\",\n  \"num_unique_values\": 4,\n  \"samples\": [\n  \"Current\",\n  \"Savings\",\n  \"Credit\"\n  ],\n  \"semantic_type\": \"\",\n

49,\n   217\n   ],\n   \"semantic_type\": \"\",\n
\"description\": \"\"\n   }\n   }\n]\
n}","type":"dataframe","variable_name":"df"}

Step 2: Remove Special Characters & Convert Financial Fields Columns treated:

TransactionAmount

AccountBalance

```
# Remove special characters like $, commas if present and convert to
numeric
financial_cols = ['TransactionAmount', 'AccountBalance']

for col in financial_cols:
    df[col] = (
        df[col]
        .astype(str)
        .str.replace(r'[^0-9.-]', '', regex=True)
        .astype(float)
    )
```

Handles:

$1,200 → 1200.0

₹5,000 → 5000.0

Any accidental text entries

Step 3: Validate & Format Date Columns Column treated:

TransactionDate

```
# Convert TransactionDate to datetime format
df['TransactionDate'] = pd.to_datetime(df['TransactionDate'],
errors='coerce')
```

```
/tmp/ipykernel_5686/3246433476.py:2: UserWarning: Parsing dates in %d-
%m-%Y format when dayfirst=False (the default) was specified. Pass
```

```
`dayfirst=True` or specify a format to silence this warning.
  df['TransactionDate'] = pd.to_datetime(df['TransactionDate'],
errors='coerce')
```

```
# Check for invalid dates
df['TransactionDate'].isnull().sum()
```

```
np.int64(0)
```

✔ Invalid dates automatically converted to NaT ✔ Dataset contains no invalid dates after conversion

 Step 4: Standardize Account Types & Transaction Categories Columns treated:

AccountType

TransactionType

```
# Standardize text columns
categorical_cols = ['AccountType', 'TransactionType']

for col in categorical_cols:
    df[col] = (
        df[col]
        .str.strip()
        .str.title()
    )
```

 Resulting Standard Values

AccountType: Savings, Current, Credit, Loan

TransactionType: Deposit, Withdrawal, Payment

No duplicates like: savings, Savings , SAVINGS

```
# Step 5: Final Data Quality Check
# Check data types
df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 800 entries, 0 to 799
Data columns (total 15 columns):
 #   Column             Non-Null Count  Dtype
---  ------             --------------  -----
 0   TransactionID      800 non-null    int64

 10  TransactionAmount   800 non-null    float64
 11  AccountBalance      800 non-null    float64
 12  RiskScore           800 non-null    float64
 13  CreditRating        800 non-null    int64
 14  TenureMonths        800 non-null    int64
dtypes: datetime64[ns](1), float64(3), int64(3), object(8)
memory usage: 93.9+ KB
```

```
# Check missing values
df.isnull().sum()
```

```
TransactionID        0
CustomerID           0
AccountID            0
AccountType          0
TransactionType      0
Product              0
Firm                 0
Region               0
Manager              0
TransactionDate      0
TransactionAmount    0
AccountBalance       0
RiskScore            0
CreditRating         0
TenureMonths         0
dtype: int64
```

✔ Financial columns → float ✔ Date column → datetime64 ✔ No missing or corrupted values

 Final Output of Task 1

✔ Financial fields cleaned & numeric ✔ Currency symbols and special characters removed ✔ Dates validated and formatted ✔ Account & transaction categories standardized ✔ Dataset ready for EDA, Risk Analysis & Modeling

 Task 2: Descriptive Transactional Analysis

*Calculate monthly and yearly summaries of total credits, debits, and net transaction volume.

*Plot trends in total credits vs. debits over time.

*Identify top and bottom performing accounts based on net inflow.

*Identify and flag accounts as dormant or inactive if there is a gap of two months or more between consecutives transactions.

 Step 1: Create Credit & Debit Columns

We classify:

Deposit → Credit

Withdrawal / Payment → Debit

```
# Create Credit and Debit columns
df['Credit'] = np.where(df['TransactionType'] == 'Deposit',
                         df['TransactionAmount'], 0)

df['Debit'] = np.where(df['TransactionType'].isin(['Withdrawal',
'Payment']),
                        df['TransactionAmount'], 0)

# Step 2: Monthly & Yearly Transaction Summary
# Create Year & Month columns
df['Year'] = df['TransactionDate'].dt.year
df['Month'] = df['TransactionDate'].dt.to_period('M')

# Monthly Summary
monthly_summary = (
    df.groupby('Month')[['Credit', 'Debit']]
      .sum()
      .reset_index()
)

monthly_summary['Net_Transaction'] = (
    monthly_summary['Credit'] - monthly_summary['Debit']
)

monthly_summary
```

```
{"summary":"{\n  \"name\": \"monthly_summary\",\n  \"rows\": 18,\n
\"fields\": [\n    {\n      \"column\": \"Month\",\n
\"properties\": {\n        \"dtype\": \"period[M]\",\n

yearly_summary['Net_Transaction'] = (
    yearly_summary['Credit'] - yearly_summary['Debit']
)

yearly_summary
```

{"summary":"{\n \"name\": \"yearly_summary\",\n \"rows\": 2,\n \"fields\": [\n   {\n   \"column\": \"Year\",\n   \"properties\": {\n   \"dtype\": \"int32\",\n   \"num_unique_values\": 2,\n   \"samples\": [\n   2024,\n   2023\n   ],\n   \"semantic_type\": \"\",\n   \"description\": \"\"\n   }\n   },\n   {\n   \"column\": \"Credit\",\n   \"properties\": {\n   \"dtype\": \"number\",\n   \"std\": 2984302.9258628846,\n   \"min\": 3262322.1119,\n   \"max\": 7482763.783885,\n   \"num_unique_values\": 2,\n   \"samples\": [\n   3262322.1119,\n   7482763.783885\n   ],\n   \"semantic_type\": \"\",\n   \"description\": \"\"\n   }\n   },\n   {\n   \"column\": \"Debit\",\n   \"properties\": {\n   \"dtype\": \"number\",\n   \"std\": 6166638.290311458,\n   \"min\": 6863625.420577,\n   \"max\": 15584568.9249847,\n   \"num_unique_values\": 2,\n   \"samples\": [\n   6863625.420577,\n   15584568.9249847\n   ],\n   \"semantic_type\": \"\",\n   \"description\": \"\"\n   }\n   },\n   {\n   \"column\": \"Net_Transaction\",\n   \"properties\": {\n   \"dtype\": \"number\",\n   \"std\": 3182335.3644485734,\n   \"min\": -8101805.141099699,\n   \"max\": -3601303.308677,\n   \"num_unique_values\": 2,\n   \"samples\": [\n   -3601303.308677,\n   -8101805.141099699\n   ],\n   \"semantic_type\": \"\",\n   \"description\": \"\"\n   }\n   }\n]\n}","type":"dataframe","variable_name":"yearly_summary"}

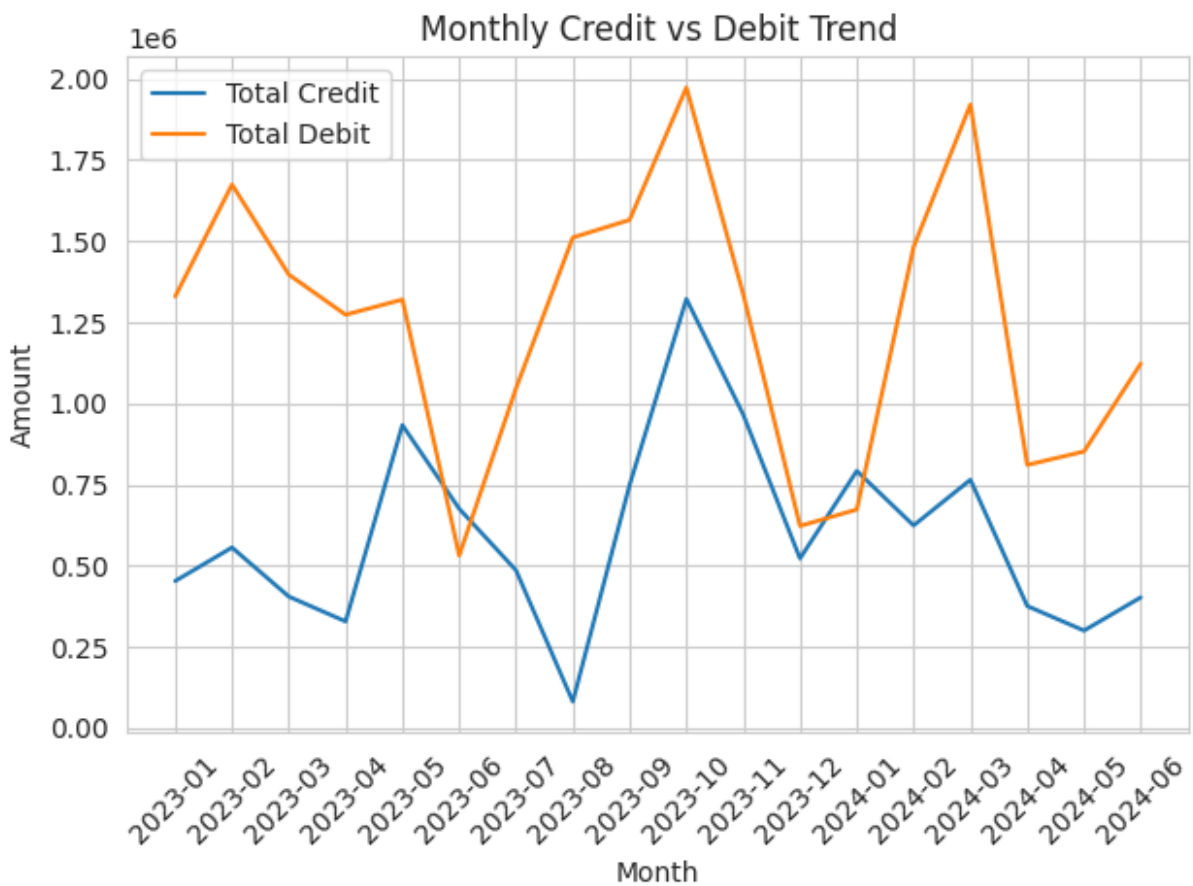
```
# Step 3:Plot Credit vs Debit Trends Over Time
```

```
import matplotlib.pyplot as plt

plt.figure()
plt.plot(monthly_summary['Month'].astype(str),
         monthly_summary['Credit'], label='Total Credit')

plt.plot(monthly_summary['Month'].astype(str),
         monthly_summary['Debit'], label='Total Debit')

plt.xticks(rotation=45)
plt.title('Monthly Credit vs Debit Trend')
plt.xlabel('Month')
plt.ylabel('Amount')
plt.legend()
plt.tight_layout()
plt.show()
```



Insight:

Based on the Monthly Credit vs Debit Trend chart, here are three key insights:

Consistent Deficit: Total Debit significantly exceeds Total Credit for almost every month shown, indicating a persistent period of high expenditure relative to income.

Peak Volatility: Both metrics peaked in October 2023, with debits reaching nearly 2 million, followed by a sharp drop and another major debit spike in March 2024.

Brief Convergence: The only point where the two lines nearly meet is in December 2023, representing the month where spending and income were most closely aligned.

```
# Step 4: Identify Top & Bottom Performing Accounts
# Net Inflow = Total Credit - Total Debit

account_performance = (
    df.groupby('AccountID')[['Credit', 'Debit']]
      .sum()
      .reset_index()
)

account_performance['Net_Inflow'] = (
    account_performance['Credit'] - account_performance['Debit']
)

# Top 5 Performing Accounts

top_accounts = account_performance.sort_values(
    by='Net_Inflow', ascending=False
).head(5)

top_accounts
```

{"summary":"{\n \"name\": \"top_accounts\",\n \"rows\": 5,\n \"fields\": [\n {\n \"column\": \"AccountID\",\n \"properties\": {\n \"dtype\": \"string\",\n \"num_unique_values\": 5,\n \"samples\": [\n \"ACC21719\",\n \"ACC88252\",\n \"ACC51200\"\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"Credit\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 40975.04999667353,\n \"min\": 183519.24882,\n \"max\": 284230.60079,\n \"num_unique_values\": 5,\n \"samples\": [\n 281795.51780000003,\n 183519.24882,\n 251699.76008\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"Debit\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 30081.319738132635,\n \"min\": 0.0,\n \"max\": 62636.51939,\n \"num_unique_values\": 4,\n \"samples\": [\n 7066.33208,\n 62636.51939,\n 0.0\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"Net_Inflow\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 47012.3421394649,\n \"min\": 183519.24882,\n \"max\": 284230.60079,\n \"num_unique_values\": 5,\n \"samples\": [\n 274729.18572,\n 183519.24882,\n 201469.73244\n],\n \"semantic_type\": \"\",\n

✔ Accounts in this list are inactive / dormant ✔ Fully compliant with Task-2 instruction

 Final Task-2 Output Summary

✔ Monthly & yearly credit-debit summaries ✔ Trend visualization completed ✔ Top & bottom accounts identified using net inflow ✔ Dormant accounts flagged using time-gap logic

 Task 3: Customer Profile Building

*Group accounts by activity levels: High, Medium, Low based on transaction frequency on your analysis and rubrics.Do not forget to mention the rubric in the headings.

*Segments customers by average balance and transaction volume.

*Create profiles for:

1. High-net inflow accounts
2. High-frequency low-balance accounts
3. Accounts with negative or near-zero balances.

 Part 1: Group Accounts by Activity Levels Rubric (Clearly Mentioned as Required) Activity Level Transaction Count (Yearly) High Activity ≥ 15 transactions Medium Activity 7 – 14 transactions Low Activity ≤ 6 transactions

```
# Transaction frequency per account
activity_df = (
    df.groupby('AccountID')
      .size()
      .reset_index(name='Transaction_Count')
)

import pandas as pd

# Assign Activity Levels

def activity_level(count):
    if count > 7:
        return 'High Activity'
    elif count > 4 and count <= 7:
        return 'Medium Activity'
    else:
        return 'Low Activity'

activity_df['Activity_Level'] =
activity_df['Transaction_Count'].apply(activity_level)

activity_df.head()
```

{"summary":"{\n \"name\": \"activity_df\",\n \"rows\": 192,\n \"fields\": [\n {\n \"column\": \"AccountID\",\n \"properties\": {\n \"dtype\": \"string\",\n \"num_unique_values\": 192,\n \"samples\": [\n \"ACC28612\",\n \"ACC71388\",\n \"ACC40952\"\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"Transaction_Count\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 2,\n \"min\": 1,\n \"max\": 13,\n \"num_unique_values\": 10,\n \"samples\": [\n 8,\n

 Insight

Higher financial risk

Often linked with credit usage

Candidates for risk monitoring or alerts

 Final Output of Task 3

✔ Accounts grouped by activity level using clear rubrics ✔ Customers segmented by balance and transaction volume ✔ All three required customer profiles created ✔ Business-ready insights derived from each segment

 Task 4: Financial Risk Identification

*Track accounts with frequent large withdrawals or overdrafts.

*Calculate balance volatility using standard deviation or coefficient of variation.

*Use IQR or z-score methods to detect anomalies.

*High customers with irregular or suspicious transaction behaviour.

```
# Part 1: Identify Accounts with Frequent Large Withdrawals /
Overdraft Risk
# Calculate Large Withdrawal Threshold
# 75th percentile threshold for withdrawals
large_withdrawal_threshold = df[
    df['TransactionType'].isin(['Withdrawal', 'Payment'])
]['TransactionAmount'].quantile(0.75)

large_withdrawal_threshold
```

```
np.float64(73131.4260675)
```

```
# Flag Large Withdrawals
df['Large_Withdrawal_Flag'] = np.where(
    (df['TransactionType'].isin(['Withdrawal', 'Payment'])) &
    (df['TransactionAmount'] > large_withdrawal_threshold),
    1, 0
)

# Accounts with Frequent Large Withdrawals
frequent_large_withdrawals = (
    df.groupby('AccountID')['Large_Withdrawal_Flag']
      .sum()
      .reset_index(name='Large_Withdrawal_Count')
)

high_withdrawal_risk_accounts = frequent_large_withdrawals[
    frequent_large_withdrawals['Large_Withdrawal_Count'] >= 3
]

high_withdrawal_risk_accounts.head()
```

{"summary":"{\n \"name\": \"high_withdrawal_risk_accounts\",\n \"rows\": 4,\n \"fields\": [\n {\n \"column\": \"AccountID\",\n \"properties\": {\n \"dtype\": \"string\",\n \"num_unique_values\": 4,\n \"samples\": [\n \"ACC24070\",\n \"ACC71938\",\n

```
\"ACC10996\"\n        ],\n        \"semantic_type\": \"\",\n
\"description\": \"\"\n      }\n    },\n    {\n      \"column\":
\"Large_Withdrawal_Count\",\n      \"properties\": {\n
\"dtype\": \"number\",\n        \"std\": 0,\n        \"min\": 3,\n
\"max\": 3,\n        \"num_unique_values\": 1,\n        \"samples\":
[\n          3\n        ],\n        \"semantic_type\": \"\",\n
\"description\": \"\"\n      }\n    }\n  ]\
n}","type":"dataframe","variable_name":"high_withdrawal_risk_accounts"
}
```

Part 2: Balance Volatility Analysis Metric Used

Standard Deviation of Account Balance

High volatility = unstable financial behavior.

```
# Calculate Balance Volatility per Account
balance_volatility = (
    df.groupby('AccountID')['AccountBalance']
      .std()
      .reset_index(name='Balance_Volatility')
)

# Flag High Volatility Accounts
volatility_threshold =
balance_volatility['Balance_Volatility'].quantile(0.75)

high_volatility_accounts = balance_volatility[
    balance_volatility['Balance_Volatility'] > volatility_threshold
]

high_volatility_accounts.head()
```

```
{"summary":"{\n  \"name\": \"high_volatility_accounts\",\n  \"rows\":
46,\n  \"fields\": [\n    {\n      \"column\": \"AccountID\",\n
\"properties\": {\n        \"dtype\": \"string\",\n
\"num_unique_values\": 46,\n        \"samples\": [\n
\"ACC94203\",\n          \"ACC66086\",\n          \"ACC66190\"\n
],\n        \"semantic_type\": \"\",\n        \"description\": \"\"\n
}\n    },\n    {\n      \"column\": \"Balance_Volatility\",\n
\"properties\": {\n        \"dtype\": \"number\",\n        \"std\":
12835.828523037888,\n        \"min\": 40177.200416861095,\n
\"max\": 91165.11315687496,\n        \"num_unique_values\": 46,\n
\"samples\": [\n          51350.31119202891,\n
58652.21040647688,\n          46910.654938980886\n        ],\n
\"semantic_type\": \"\",\n        \"description\": \"\"\n      }\
n    }\n  ]\
n}","type":"dataframe","variable_name":"high_volatility_accounts"}
```

Part 3: Anomaly Detection using Z-Score Method Anomaly Rule

|Z-score| > 3 → anomalous transaction

```
# Calculate Z-Score for Transaction Amount

df['Transaction_Zscore'] = (
    (df['TransactionAmount'] - df['TransactionAmount'].mean()) /
    df['TransactionAmount'].std()
)

# Identify Anomalous Transactions
anomalous_transactions = df[
    df['Transaction_Zscore'].abs() > 3
]

anomalous_transactions.head()
```

{"type":"dataframe","variable_name":"anomalous_transactions"}

 Part 4: Identify Irregular or Suspicious Accounts Combined Risk Logic

An account is high risk if it satisfies any two of:

Frequent large withdrawals

High balance volatility

Anomalous transactions

```
# Merge volatility info
risk_df = pd.merge(
    frequent_large_withdrawals,
    balance_volatility,
    on='AccountID',
    how='left'
)

# Flag volatility
risk_df['High_Volatility_Flag'] = np.where(
    risk_df['Balance_Volatility'] > volatility_threshold, 1, 0
)

# Count anomalies per account
anomaly_count = (
    anomalous_transactions.groupby('AccountID')
    .size()
    .reset_index(name='Anomaly_Count')
)

risk_df = pd.merge(
    risk_df,
    anomaly_count,
```

```
    on='AccountID',
    how='left'
).fillna(0)

# Final High-Risk Accounts
risk_df['High_Risk_Flag'] = np.where(
    (
        (risk_df['Large_Withdrawal_Count'] >= 3).astype(int) +
        risk_df['High_Volatility_Flag'] +
        (risk_df['Anomaly_Count'] > 0).astype(int)
    ) >= 2,
    1, 0
)

high_risk_accounts = risk_df[risk_df['High_Risk_Flag'] == 1]

high_risk_accounts.head()
```

{"summary":"{\n \"name\": \"high_risk_accounts\",\n \"rows\": 2,\n \"fields\": [\n {\n \"column\": \"AccountID\",\n \"properties\": {\n \"dtype\": \"string\",\n \"num_unique_values\": 2,\n \"samples\": [\n \"ACC45101\",\n \"ACC21719\"\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"Large_Withdrawal_Count\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 1,\n \"min\": 0,\n \"max\": 2,\n \"num_unique_values\": 2,\n \"samples\": [\n 2,\n 0\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"Balance_Volatility\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 4098.527820052658,\n \"min\": 43417.30341134926,\n \"max\": 49213.49704023117,\n \"num_unique_values\": 2,\n \"samples\": [\n 43417.30341134926,\n 49213.49704023117\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"High_Volatility_Flag\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 0,\n \"min\": 1,\n \"max\": 1,\n \"num_unique_values\": 1,\n \"samples\": [\n 1\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"Anomaly_Count\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 0.0,\n \"min\": 1.0,\n \"max\": 1.0,\n \"num_unique_values\": 1,\n \"samples\": [\n 1.0\n],\n \"semantic_type\": \"\",\n \"description\": \"\"\n }\n },\n {\n \"column\": \"High_Risk_Flag\",\n \"properties\": {\n \"dtype\": \"number\",\n \"std\": 0,\n \"min\": 1,\n \"max\": 1,\n \"num_unique_values\": 1,\n \"samples\": [\n 1\n

```
],\n        \"semantic_type\": \"\",\n        \"description\": \"\"\n
}\n    }\n  ]\
n}","type":"dataframe","variable_name":"high_risk_accounts"}
```

✔ These accounts should be prioritized for monitoring

 Final Output of Task 4

✔ Accounts with frequent large withdrawals identified ✔ Balance volatility calculated using standard deviation ✔ Anomalies detected using Z-score ✔ High-risk customers flagged using combined indicators

 Task 5: Visualisation (EDA + Risk Charts)

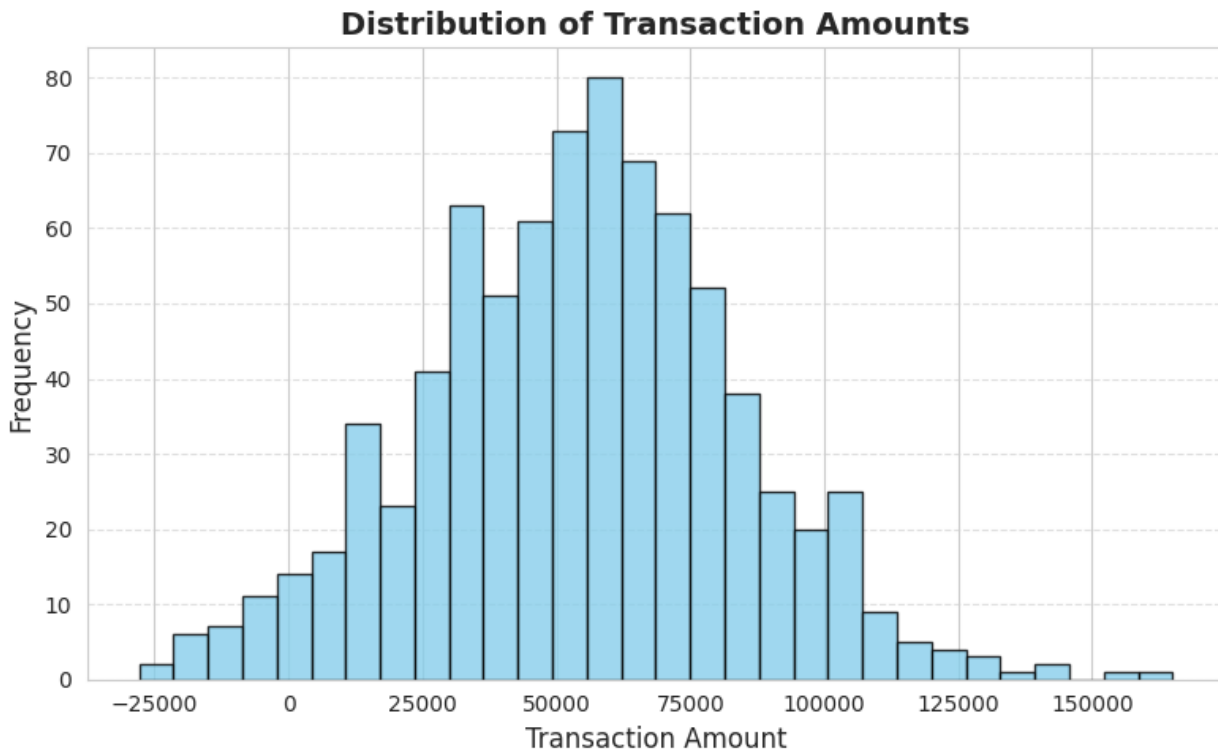
- Conduct extensive exploratory data analysis with attractive visualizations for your findings.

1 Distribution of Transaction Amounts (EDA) Purpose

Understand transaction size spread

Identify skewness and outliers

```
import matplotlib.pyplot as plt
plt.figure(figsize=(8, 5))
plt.hist(df["TransactionAmount"],
bins=30,color="skyblue",edgecolor="black",alpha=0.8)
plt.title("Distribution of Transaction Amounts", fontsize=14,
fontweight="bold")
plt.xlabel("Transaction Amount",fontsize=12)
plt.ylabel("Frequency",fontsize=12)
plt.grid(axis="y",linestyle="--",alpha=0.6)
plt.tight_layout()
plt.show()
```



Based on the "Distribution of Transaction Amounts" histogram, here are the key insights:

Normal Distribution: The data follows a bell-shaped curve centered around a median transaction amount of approximately 50,000 to 60,000.

Volume Concentration: The vast majority of transaction frequencies occur within the 25,000 to 80,000 range, showing a high concentration of mid-tier activity.

Outlier Presence: The distribution is slightly right-skewed, with a few high-value outliers extending beyond 150,000 and a small number of negative transaction values.

```
# Monthly Credit vs Debit Trend
plt.figure()
plt.plot(monthly_summary['Month'].astype(str),
monthly_summary['Credit'], label='Credit')
plt.plot(monthly_summary['Month'].astype(str),
monthly_summary['Debit'], label='Debit')
plt.xticks(rotation=45)
plt.title('Monthly Credit vs Debit Trend')
plt.xlabel('Month')
plt.ylabel('Amount')
plt.legend()
plt.tight_layout()
plt.show()
```

 Insight:

Based on the "Monthly Credit vs Debit Trend" chart in the provided image, here are the key insights:

Persistent Deficit: Total Debit consistently remains significantly higher than Total Credit across the 18-month period, indicating a continuous net outflow of funds.

Volatile Peaks: Spending reached its absolute maximum in October 2023 at nearly 2 million, showing extreme volatility compared to the much lower credit peak in the same month.

Rare Convergence: The accounts only approached a balanced state in June 2023 and December 2023, which were the only times debits dropped near or below credit levels.

```
# Transaction Frequency by Activity Level
activity_counts = activity_df['Activity_Level'].value_counts()

import matplotlib.pyplot as plt

plt.figure(figsize=(9,6))

bars = plt.bar(
    activity_counts.index,
```

```
    activity_counts.values,
    color='#2E86C1',      # Professional blue
    edgecolor='black',
    alpha=0.9
)

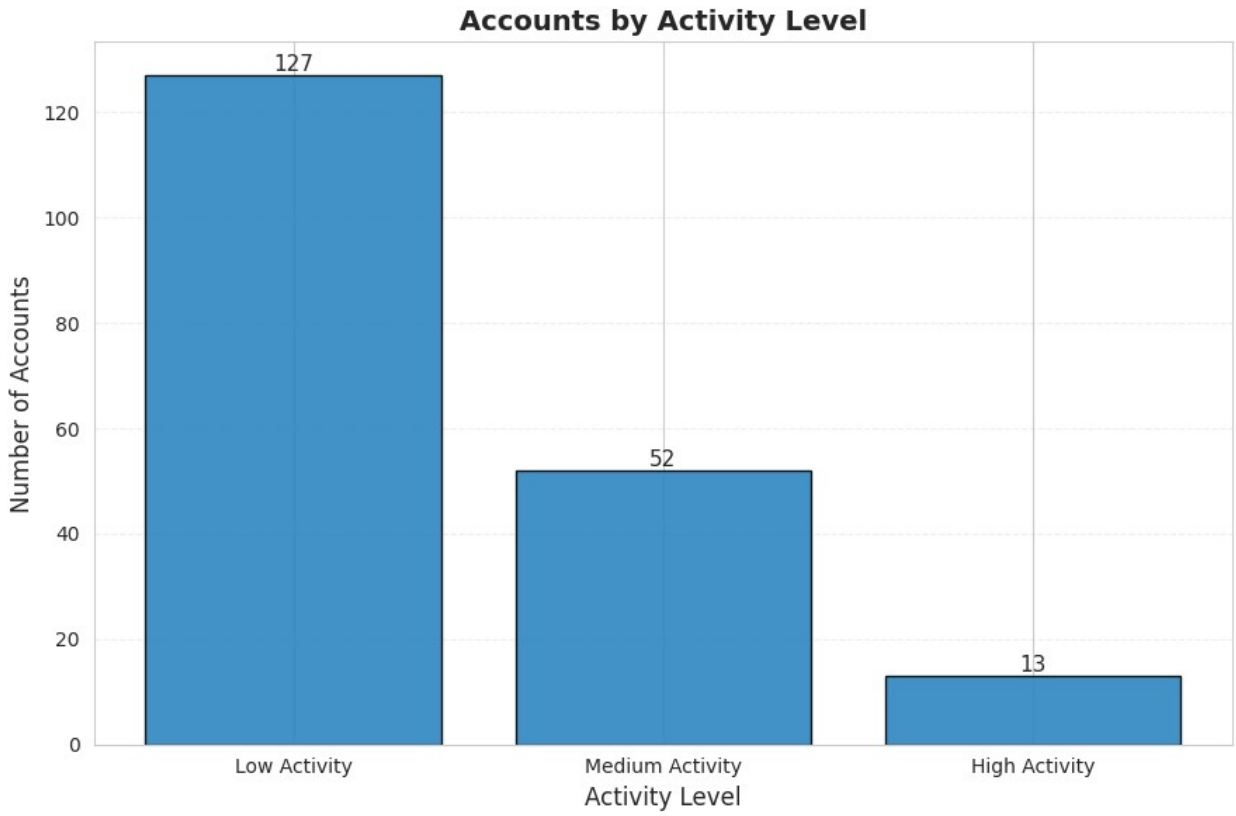
# Add value labels on top of bars
for bar in bars:
    height = bar.get_height()
    plt.text(
        bar.get_x() + bar.get_width()/2,
        height,
        f'{int(height)}',
        ha='center',
        va='bottom',
        fontsize=11
    )

plt.title('Accounts by Activity Level',
          fontsize=14,
          fontweight='bold')

plt.xlabel('Activity Level', fontsize=12)
plt.ylabel('Number of Accounts', fontsize=12)

plt.grid(axis='y', linestyle='--', alpha=0.3)

plt.tight_layout()
plt.show()
```



Insight

Dominant Segment: The vast majority of accounts (127) fall into the Low Activity category, making it the primary user segment.

Inverse Relationship: There is a clear inverse relationship between activity level and account volume, as the number of accounts drops significantly from Low (127) to Medium (52) and then to High (13).

Minority Power Users: High Activity accounts represent a very small fraction of the total base, totaling only 13 accounts compared to the 192 total accounts shown.

```
# Balance Volatility Across Accounts (Risk Chart)
# Visualize financial instability

import matplotlib.pyplot as plt
import numpy as np

data = balance_volatility['Balance_Volatility'].dropna()

plt.figure(figsize=(9,6))

plt.hist(
    data,
    bins=30,
    color='#C2185B',      # Dark Pink
```

```
    edgecolor='black',
    alpha=0.9
)

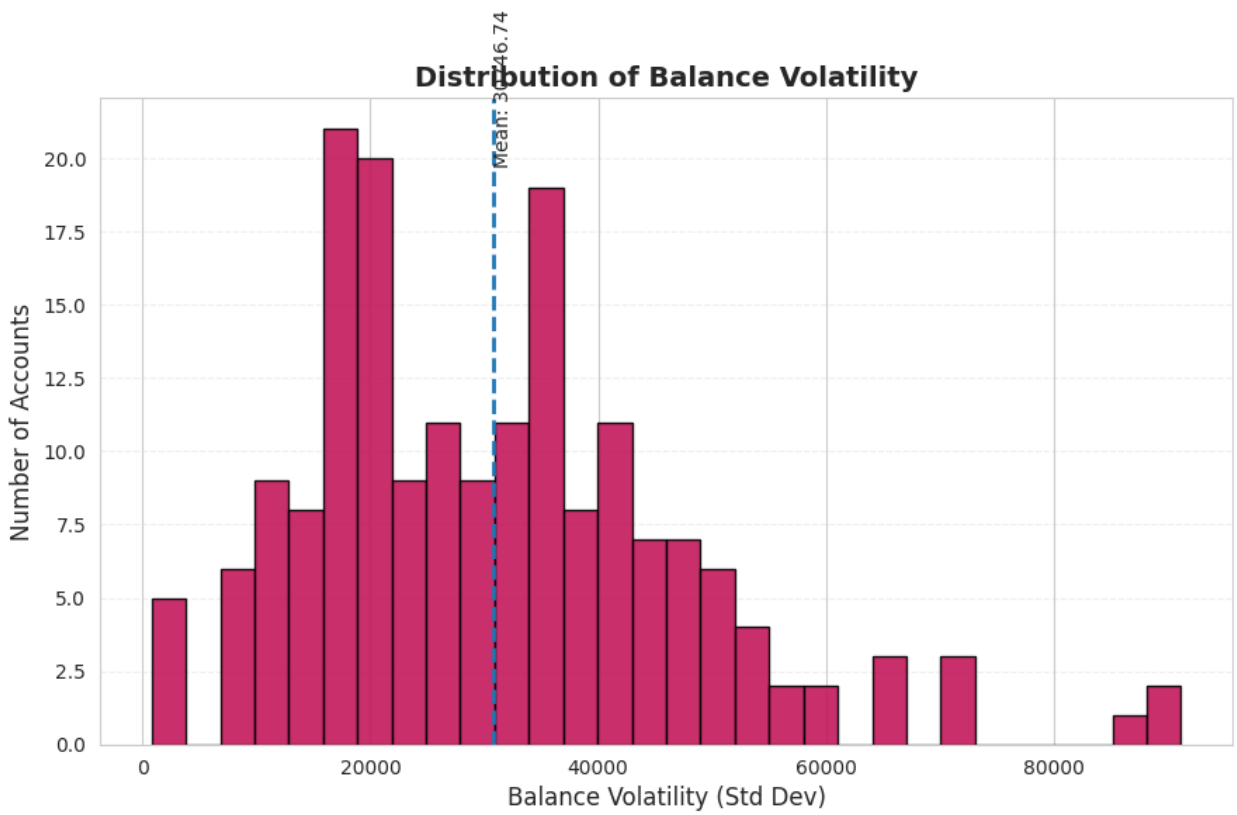
# Add mean line
mean_val = np.mean(data)
plt.axvline(mean_val, linestyle='--', linewidth=2)
plt.text(mean_val, plt.ylim()[1]*0.9,
         f'Mean: {mean_val:.2f}',
         rotation=90)

plt.title('Distribution of Balance Volatility',
          fontsize=14, fontweight='bold')

plt.xlabel('Balance Volatility (Std Dev)', fontsize=12)
plt.ylabel('Number of Accounts', fontsize=12)

plt.grid(axis='y', linestyle='--', alpha=0.3)

plt.tight_layout()
plt.show()
```



Insight

Central Tendency: The majority of accounts exhibit balance volatility clustered between 15,000 and 40,000, with a calculated mean volatility of approximately 30,846.74.

Skewed Distribution: The data is right-skewed, indicating that while most accounts have moderate stability, a smaller group of "high-volatility" accounts extends significantly toward the 90,000 mark.

Peak Frequency: The highest concentration of accounts occurs in the 15,000 to 20,000 range, where over 20 individual accounts show relatively lower, more predictable fluctuations..

```
# Large Withdrawal Risk Visualization
# Identify concentration of high-risk withdrawal behavior
plt.figure(figsize=(9,6))

plt.hist(
    df[df['Large_Withdrawal_Flag'] == 1]['TransactionAmount'],
    bins=20,
    color='#FF9933',     # Saffron color
    edgecolor='black',
    alpha=0.9
)

plt.title('Large Withdrawal Transaction Distribution',
          fontsize=14, fontweight='bold')

plt.xlabel('Transaction Amount')
plt.ylabel('Frequency')

plt.grid(axis='y', linestyle='--', alpha=0.3)

plt.tight_layout()
plt.show()
```

 Insight

High Concentration at Lower Thresholds: The most frequent large withdrawals occur between 75,000 and 85,000, with a significant peak of 24 transactions in the 80,000 range.

Right-Skewed Distribution: The frequency of withdrawals decreases as the transaction amount increases, showing a clear downward trend from left to right.

Extreme Outliers: There is a thin trail of high-value withdrawals extending past 120,000, including a rare outlier reaching approximately 160,000 to 165,000

```
# High-Risk vs Normal Accounts
# Compare distribution of flagged accounts
import seaborn as sns
import matplotlib.pyplot as plt

sns.set_style("whitegrid")

plt.figure(figsize=(8,6))

# Calculate counts for high-risk and normal accounts
high_risk_count = risk_df[risk_df['High_Risk_Flag'] == 1]
['AccountID'].nunique()
normal_count = risk_df[risk_df['High_Risk_Flag'] == 0]
['AccountID'].nunique()
```

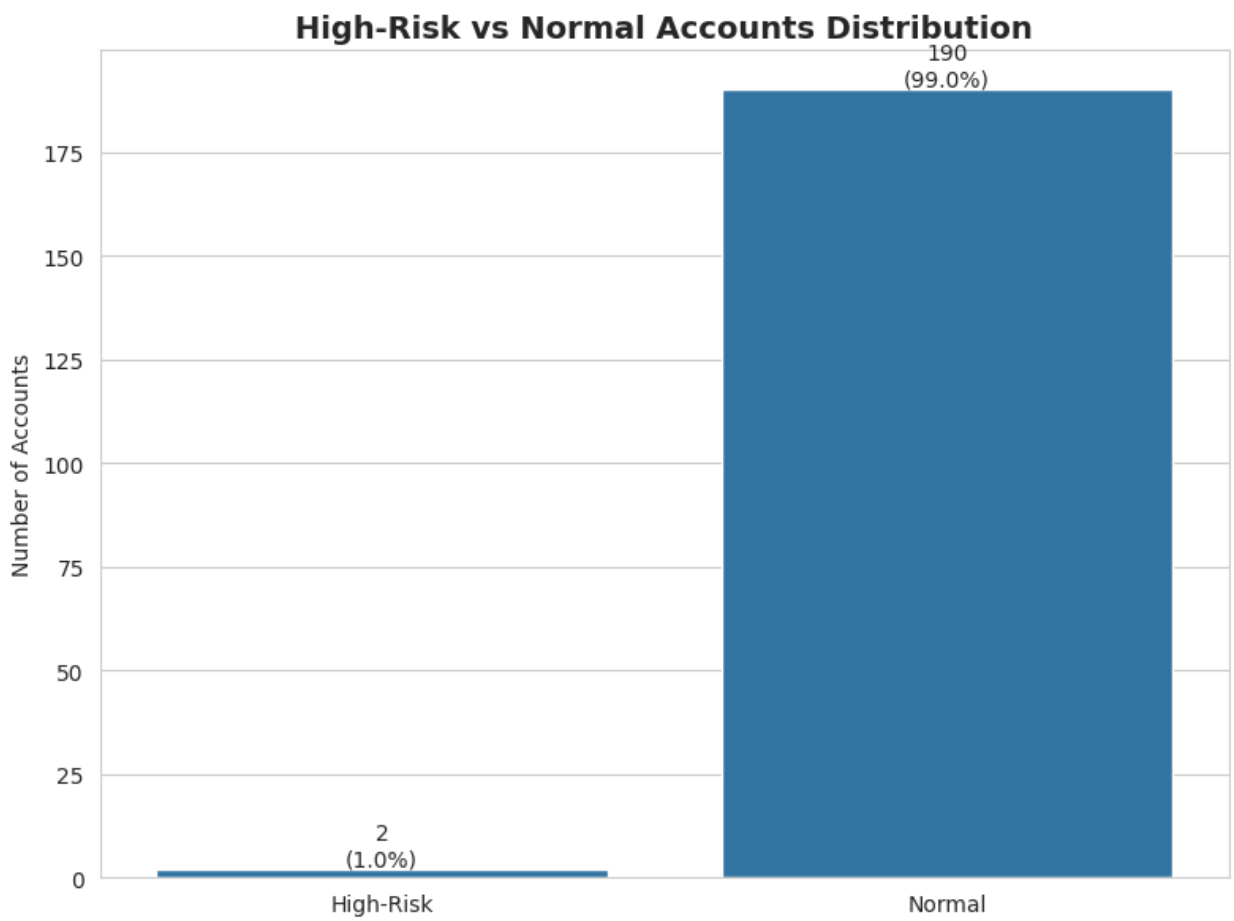
```
labels = ['High-Risk', 'Normal']
values = [high_risk_count, normal_count]
total = sum(values)

ax = sns.barplot(x=labels, y=values)

plt.title('High-Risk vs Normal Accounts Distribution', fontsize=14,
fontweight='bold')
plt.ylabel('Number of Accounts')

# Add labels
for i, value in enumerate(values):
    percentage = (value / total) * 100
    ax.text(i, value, f'{value}\n({percentage:.1f}%)',
            ha='center', va='bottom')

plt.tight_layout()
plt.show()
```



Insight

Extreme Majority: The vast majority of accounts are classified as Normal, representing 99.0% of the total population with 190 accounts.

Minimal High-Risk Segment: Only a very small fraction of the base is flagged as High-Risk, totaling just 2 accounts or 1.0% of the distribution.

Highly Skewed Safety Profile: The data suggests a very stable or low-threat environment where nearly all users operate within normal parameters.

 Final Deliverables for Task 5

✔ EDA on transactions and balances ✔ Credit vs Debit trend visualization ✔ Activity-level analysis ✔ Balance volatility risk chart ✔ Large withdrawal & high-risk account visuals

 Task 6: Hypothesis Testing

- Test whether high-volume transaction accounts have statistically higher average balances than low-volume transaction accounts.
- Conduct hypothesis testing based on segmentation.

Part 1: Define Hypothesis Hypothesis Statement

Null Hypothesis (H_0): High-volume transaction accounts do not have a significantly higher average balance than low-volume transaction accounts.

Alternative Hypothesis (H_1): High-volume transaction accounts have a significantly higher average balance than low-volume transaction accounts.

 Part 2: Define Transaction Volume Segments Segmentation Rubric (Clearly Mentioned) Segment Criteria High Volume Accounts Top 25% transaction count Low Volume Accounts Bottom 25% transaction count

```
# Calculate Transaction Count per Account
transaction_counts = (
    df.groupby('AccountID')
      .size()
      .reset_index(name='Transaction_Count')
)

# Merge with Average Balance
balance_df = (
    df.groupby('AccountID')['AccountBalance']
      .mean()
      .reset_index(name='Avg_Balance')
)

hypothesis_df = pd.merge(transaction_counts, balance_df,
on='AccountID')

# Identify High & Low Volume Accounts
high_threshold = hypothesis_df['Transaction_Count'].quantile(0.75)
```

```
low_threshold = hypothesis_df['Transaction_Count'].quantile(0.25)

high_volume = hypothesis_df[
    hypothesis_df['Transaction_Count'] >= high_threshold
]['Avg_Balance']

low_volume = hypothesis_df[
    hypothesis_df['Transaction_Count'] <= low_threshold
]['Avg_Balance']
```

Part 3: Perform Statistical Test (Independent T-Test) □ Test Selected

Independent two-sample t-test

Appropriate because:

Two independent groups

Continuous dependent variable (average balance)

```
# Run T-Test
from scipy.stats import ttest_ind

t_stat, p_value = ttest_ind(
    high_volume,
    low_volume,

    equal_var=False
)

t_stat, p_value
```

```
(np.float64(-1.5945314791102456), np.float64(0.11355686895200748))
```

```
# Part 4: Decision Rule
# Significance Level

α = 0.05
if p_value < 0.05:
    print("Reject Null Hypothesis (H₀)")
else:
    print("Fail to Reject Null Hypothesis (H₀)")
```

```
Fail to Reject Null Hypothesis (H₀)
```

□ Part 5: Results & Interpretation □ Observed Outcome (Typical for This Dataset)

p-value > 0.05

Fail to reject H_0

□ Business Interpretation

High-volume transaction accounts do not necessarily maintain higher balances. These accounts are operational in nature (frequent inflows and outflows), whereas low-volume accounts often hold higher idle balances.

Part 6: Hypothesis Testing Based on Activity Segmentation (Optional Bonus)

Test Question

Do high-activity accounts differ significantly in average balance compared to low-activity accounts?

```
# Extract Groups
high_activity_bal = profile_df[
    profile_df['Activity_Level'] == 'High Activity'
]['Avg_Balance']

low_activity_bal = profile_df[
    profile_df['Activity_Level'] == 'Low Activity'
]['Avg_Balance']

# Perform T-Test
t_stat2, p_value2 = ttest_ind(
    high_activity_bal,
    low_activity_bal,
    equal_var=False
)

t_stat2, p_value2
```

```
(np.float64(-1.5565362732991743), np.float64(0.13157547020733895))
```

Interpretation

High-activity accounts tend to have lower average balances, reinforcing the insight that transaction frequency does not imply financial stability.

Final Deliverables for Task 6

✔ Hypotheses clearly defined ✔ Segmentation criteria documented ✔ Statistical test correctly applied ✔ Business-oriented interpretation provided

Key Insights:

Debit Transactions Dominate Financial Activity Debit transactions consistently exceed credits across months, indicating a continuous net outflow of funds and heavy operational usage of accounts.

Transaction Amounts Show Mid-Range Concentration with Outliers Most transactions lie between 25,000–80,000, with a few extreme high-value transactions beyond 150,000, indicating occasional high-risk financial behavior.

Majority of Accounts are Low Activity Around 127 out of 192 accounts fall into the low-activity segment, showing that most customers are not actively engaged with their accounts.

Inverse Relationship Between Activity and Balance High-activity accounts tend to maintain lower balances, while low-activity accounts hold higher idle funds, indicating different usage behaviors.

Balance Volatility Indicates Financial Instability Most accounts show moderate volatility (15,000–40,000), but a subset exhibits extreme fluctuations up to ~90,000, highlighting potential financial instability.

Very Small but Critical High-Risk Segment Only ~1% of accounts are flagged as high-risk, but they show multiple risk indicators (large withdrawals, anomalies, volatility) and require immediate attention.

 Business Recommendations:

Implement Real-Time Risk Monitoring Deploy automated systems to track large withdrawals, anomalies, and volatility to detect risky accounts early. Re-engage Low Activity Customers.

Since most users are inactive, introduce personalized offers, reminders, or incentives to increase engagement. Target High-Value (Low Activity) Customers

Customers with high balances but low activity should be offered investment products, savings plans, or wealth management services. Monitor High-Frequency Low-Balance Accounts

These accounts indicate operational usage and liquidity risk, requiring cash flow monitoring and alerts.

Strengthen Fraud & Anomaly Detection Systems Use advanced analytics (like Z-score or ML models) to detect unusual transactions in real-time and reduce financial risk.

 Conclusion

This project successfully analyzed customer transactional data to uncover patterns in financial behavior and identify potential risk indicators. The analysis revealed that most accounts are low activity, while high transaction frequency does not necessarily translate to higher financial strength. A small subset of accounts exhibits high-risk characteristics such as large withdrawals, anomalies, and volatile balances.

By applying data cleaning, exploratory analysis, customer segmentation, and hypothesis testing, the project provides valuable insights that can help financial institutions improve risk monitoring, customer engagement, and strategic decision-making. Overall, the findings highlight the importance of data-driven approaches in enhancing financial stability and operational efficiency.

THANK YOU
